# Contents

	<b>Foreword</b>	v
	<b>Preface</b>	vii
1	<b>Mechanisms of Virus Resistance in Plants</b> M. E. Chrissie Rey and Vincent N. Fondong	1
2	<b>Role of Host Transcription Factors in Modulating Defense Response During Plant–Virus Interaction</b> Saurabh Pandey, Pranav P. Sahu, Ritika Kulshreshtha and Manoj Prasad	25
3	<b>Surfacing the Role of Epigenetics in Host–Virus Interaction</b> Namisha Sharma, Pranav P. Sahu, Ritika Kulshreshtha and Manoj Prasad	55
4	<b>Molecular Markers as Tools for Identification and Introgression of Virus-Resistant Genes</b> Mamta Sharma, Avijit Tarafdar, U. S. Sharath Chandran, Devashish R. Chobe and Raju Ghosh	87
5	<b>Genetic Engineering for Virus Resistance in Plants: Principles and Methods</b> Basavaprabhu L. Patil	103
6	<b>Tools and Techniques for Production of Double-stranded RNA and its Application for Management of Plant Viral Diseases</b> Andreas E. Voloudakis, Maria C. Holeva, Athanasios Kaldis and Dongho Kim	119
7	<b>Transgenic Virus-Resistant Papaya: Current Status and Future Trends</b> Gustavo Fermin, Paula Tennant and Sudeshna Mazumdar-Leighton	141
8	<b>Development and Delivery of Transgenic Virus-resistant Cassava in East Africa</b> Henry Wagaba, Andrew Kiggundu and Nigel Taylor	159
9	<b>Viruses Infecting Rice and their Transgenic Control</b> Gaurav Kumar, Shweta Sharma and Indranil Dasgupta	177
10	<b>Whitefly-transmitted Begomoviruses and Advances in the Control of their Vectors</b> Surapathrudu Kanakala and Murad Ghanim	201

11	<b>Virus-resistant Transgenic Tomato: Current Status and Future Prospects</b> S.V. Ramesh and Shelly Praveen	221
12	<b>Management of Geminiviruses Focusing on Small RNAs in Tomato</b> Archana Singh and Sunil Kumar Mukherjee	235
13	<b>Viruses Infecting Banana and their Transgenic Management</b> Ramasamy Selvarajan, Chelliah Anuradha, Velusamy Balasubramanian, Sivalingam Elayabalan and Kanicheluam Prasanya Selvam	255
14	<b>Virus-induced Gene Silencing (VIGS) and its Applications</b> Deep Ratan Kumar, Tejohan Saini and Radhamani Anandalakshmi	277
15	<b>Possible Strategies for Establishment of VIGS Protocol in Chickpea</b> Ranjita Sinha and Muthappa Senthil-Kumar	329
	<b>Index</b>	345

# Foreword

In 1986, the first report on the use of genetic engineering to control *Tobacco mosaic virus* in tobacco plants was published and it opened the gate to a flood of publications for the possible control of many viruses in many hosts. At that time, this concept of engineering virus resistance was a breakthrough. Controlling plant viruses has always been a big challenge to breeders, and suddenly it was possible to control almost any virus in any crop through genetic engineering! Evidently, over the years many natural sources of resistance for numerous plant viruses had been identified; however, combining these resistance sources with other traits was always a challenge to breeders. Therefore, genetic engineering appeared as *the* solution to control plant viruses!

But three decades later, we have to acknowledge that we have not seen the expected revolution in farmers' fields. On the contrary, we have seen the emergence and outbreak of many new and known plant viral diseases, threatening food security. Even though some plants have been engineered with multiple virus resistance, they have never been commercialized. The engineered papaya with immunity to *Papaya ringspot virus* remains the most successful example of commercialization of virus-resistant transgenics.

The failure to commercialize virus-resistant transgenics is the result not of technical or scientific problems or any sort of biological barrier, but mostly of political pressures from so-called ecological groups. In the meantime, improved technologies were developed and transferred to new crops and novel viruses, and in some instances made real scientific breakthroughs. However, the vested interests of these groups of fanatics, with a false claim of saving the earth's ecology, raised biosafety standards to the point where only large

multinationals could afford them, which de facto prevented the application of these technologies to many important food crops in the world.

In the beginning of the twenty-first century, the genomic revolution brought new hopes to control plant viruses by harnessing natural genes of resistance. Whole-genome sequencing of many plants, along with scores of novel DNA technologies, facilitated the use of modern tools in gene discovery for virus resistance. However, the introgression of these resistant loci was restricted due to their multigenic or recessive nature, making it difficult to transfer them to a suitable genetic background without using genetic engineering technologies.

Recently, the discovery and use of gene-editing technologies such as CRISPR/Cas9 and TALENs may now allow plant virologists, genomics experts and breeders to work together for a breakthrough in controlling plant viruses. This can be a reality only if these technologies are not considered to be GM- technologies by policy makers.

This book, *Genes, Genetics and Transgenics for Virus Resistance in Plants*, provides a very nice update on the status of current knowledge on the use of genetic engineering and other biotechnological strategies for the control of plant viruses. It is hoped that this information will be used in conjunction with the latest gene technologies to achieve the urgently needed scientific breakthroughs for the successful control of plant viruses, ultimately for the benefit of humankind.

# Preface

Viral diseases of crop plants cause significant yield losses, which is a major threat to global food security. Unlike other pests and pathogens, the only remedy available for control of plant viral diseases is through introgression of resistance trait, either through conventional breeding or through genetic engineering. Availability of few natural sources of virus resistance has hampered development of virus-resistant crop plants through conventional crop improvement methods. Thus genetic engineering for virus resistance is the sole option available for effective management of viral diseases. Since the first report on transgenic virus resistance in tobacco in 1986, huge progress has been made in our understanding of the molecular basis of virus resistance, complimented by the significant improvement in the tools and techniques used for genetic engineering. Despite major advancements in plant genomics and transgenics, there has been no commercialization of virus-resistant transgenic crops, except transgenic papaya. Thus, to provide an up-to-date reference book on genes, genetics and transgenics for virus resistance in plants for students, faculties and researchers, here we have compiled 15 diverse chapters. In the first chapter the

current knowledge on mechanisms of virus resistance in plants is discussed, followed by a chapter on the role of host transcription factors in modulating defence response during plant-virus interaction, and a chapter on the role of epigenetics in host-virus interactions. There is a chapter on how molecular markers could be employed as tools for identification and introgression of virus-resistant genes. This book also thoroughly discusses the principles and methods involved in the genetic engineering for virus resistance in plants. The book also elaborates on topical application of double-stranded RNA for control of plant viral diseases, without having to develop transgenic plants. Further, the book deals with individual crops such as papaya, cassava, rice, tomato, and banana, for which virus resistance has been accomplished by employing different transgenic technologies. The management of whitefly-transmitted begomoviruses and advances in the control of their vectors is also covered as an independent chapter. Virus-induced gene silencing (VIGS), another frontier area of research in which virus-derived silencing vectors are extensively used in gene function studies and functional genomics, is also discussed elaborately.

**ABSTRACT** Many examples of extreme virus resistance and posttranscriptional gene silencing of endogenous or re-porter genes have been described in transgenic plants containing sense or antisense transgenes. In these cases of either cosuppression or antisense suppression, there appears to be induction of a surveillance system within the plant that specifically degrades both the transgene and target RNAs. We show that transforming plants with virus or reporter gene constructs that produce RNAs capable of duplex formation confer virus immunity or gene silencing on the plants.

### 5 Plant breeding for disease resistance.

#### 5.1 GM or transgenic engineered disease resistance.

##### 5.1.1 PRR transfer.

##### 5.1.2 Stacking.

Plants in both natural and cultivated populations carry inherent disease resistance, but this has not always protected them. The late blight Great Famine of Ireland of the 1840s was caused by the oomycete *Phytophthora infestans*. Expression of viral coat protein gene sequences conferred virus resistance via small RNAs. This proved to be a widely applicable mechanism for inhibiting viral replication.[41] Combining coat protein genes from three different viruses, scientists developed squash hybrids with field-validated, multiviral resistance. Similar levels of resistance to this variety of viruses had not been achieved by conventional breeding. Savenkov and Valkonen produced transgenic tobacco plants resistant to Potato virus A (PVA, genus Potyvirus) and examined whether the resistance to PVA was affected by infection of the transgenic plants with Potato virus Y (PVY), another potyvirus that was known to suppress RNA silencing through its HC-Pro protein (D'Azavedo & Ding, 2008; Ding & Voinnet, 2007). It was concluded that RNA-silencing mediated resistance in transgenic plants against viruses may be suppressed by infection of the plants with heterologous viruses that encode suppressors of gene silencing (Savenkov & Valkonen, 2001). Not equally definite was the outcome from the studies of Mitter et al. *Virus Gene*. Viral genes are introduced into bacteria, yeast, plants, or cultured cells where the desired protein is produced. From: *Viruses*, 2017. Related terms H.V. Davies, in *Developments in Plant Genetics and Breeding*, 2000. *Viruses*. Viral genes: Whilst the search for the identity of new sources of resistance continues to be a major challenge, the success of genetic engineering for virus resistance must still represent one of the major success stories in plant biotechnology (Davies 1996 and references therein). New sources of antiviral transgenes that give resistance continue to be discovered. One of the best-documented approaches is coat protein (CP)-mediated resistance, now widely effective against PVX, PVY, PLRV and mop top. *Transgenic Plant Salt Stress Drought Stress Salt Tolerance Drought Tolerance*.
