Human physiology is a life science and a branch of animal physiology. It is specifically the study of how systems of the body function in a well state, and this analysis of function is often at the cellular level, not of single cells but of how cells work in concert to achieve a normal state of function. Basic human physiology studies the body's systems that function appropriately and as expected, while other disciplines like pathophysiology may look at the way body systems develop disease in attempts to find insight into how to cure diseases. Human Physiology is an international peer reviewed journal aimed at promoting the integration of theory, methods, and research in human physiology. The journal publishes original studies on brain function and its disturbances, including neural mechanisms subserving perception, learning, memory, emotion, and language. Human Physiology provides a forum for many areas of physiology, such as respiration, circulation, the blood system, motor functions, and digestion, as well as sport and occupational physiology. Human physiology is the science of the mechanical, physical, and biochemical functions of normal humans or human tissues or organs. The principal level of focus of physiology is at the level of organs and systems. Note: The above text is excerpted from the Wikipedia article "Human physiology", which has been released under the GNU Free Documentation License. advertisement. For more information, see the following related content on ScienceDaily Physiology The word physiology is from the Ancient Greek *phusis* (phusiology, "natural philosophy") and it is the study of how organisms perform their vital functions. An example is the study of how a muscle contracts or the force contracting muscles exert on the skeleton. It was introduced by French physician Jean Fernery in 1552. Physiology is built upon a tripod of sciences: physics, chemistry, and anatomy. Category:Human physiology. From Wikipedia, the free encyclopedia. Jump to navigation Jump to search.
